

# Strong Data Processing Constant is Achieved by Binary Inputs

Or Ordentlich and Yury Polyanskiy

## Abstract

For any channel  $P_{Y|X}$  the strong data processing constant is defined as the smallest number  $\eta_{KL} \in [0, 1]$  such that  $I(U; Y) \leq \eta_{KL} I(U; X)$  holds for any Markov chain  $U - X - Y$ . It is shown that the value of  $\eta_{KL}$  is given by that of the best binary-input subchannel of  $P_{Y|X}$ . The same result holds for any  $f$ -divergence, verifying a conjecture of Cohen, Kemperman and Zbaganu (1998).

Consider an arbitrary channel  $P_{Y|X} : \mathcal{X} \rightarrow \mathcal{Y}$  with countable  $\mathcal{X}$ . We define the strong data processing inequality (SDPI) constant [1]

$$\eta_{KL} = \sup \frac{D(P_{Y|X} \circ P \| P_{Y|X} \circ Q)}{D(P \| Q)}, \quad (1)$$

where optimization is over all pairs of distributions on  $\mathcal{X}$ , denoted  $P, Q \in \mathcal{P}(\mathcal{X})$ , such that  $0 < D(P \| Q) < \infty$ , and  $P_{Y|X} \circ P$  is the distribution of the output  $Y$  when the input  $X$  is distributed according to  $P \in \mathcal{P}(\mathcal{X})$ . We refer to [2] for a survey of the properties and importance of the SDPI, in particular for showing equivalence to the definition in the abstract, and advertise [3] as a recent application in statistics.

When the input alphabet  $\mathcal{X}$  is binary, the value of  $\eta_{KL}$  is relatively easy to compute, cf. [2, Appendix B]. Here we prove that for general  $\mathcal{X}$  determination of  $\eta_{KL}$  can be reduced to the binary case.

*Theorem 1:* Optimization in (1) can be restricted to pairs  $P, Q$  supported on two points in  $\mathcal{X}$  (same for both).

**Proof.** For two distributions  $P$  and  $Q$  on  $\mathcal{X}$  and  $\lambda \in (0, 1)$  define

$$L_\lambda(P, Q) \triangleq D(P_{Y|X} \circ P \| P_{Y|X} \circ Q) - \lambda D(P \| Q).$$

We assume that  $0 < D(P \| Q) < \infty$  as required by the definition of  $\eta_{KL}$ . We will show that we can find two distributions  $\hat{P}$  and  $\hat{Q}$  where  $\hat{Q}$  is supported on two letters in  $\text{supp}(Q) \triangleq \{x \in \mathcal{X} : Q(x) > 0\}$ , and  $L_\lambda(\hat{P}, \hat{Q}) \geq L_\lambda(P, Q)$ . This implies the statement, since  $\eta_{KL} = \sup \{\lambda : \sup_{P, Q} L_\lambda(P, Q) \geq 0\}$ .

To that end define the convex set of distributions

$$\mathcal{S} \triangleq \left\{ \hat{Q} : \text{supp}(\hat{Q}) \subseteq \text{supp}(Q), \sum_{x \in \text{supp}(Q)} \frac{P(x)}{Q(x)} \cdot \hat{Q}(x) = 1 \right\}.$$

Consider the function  $g : \mathcal{S} \rightarrow \mathbb{R}$  defined as  $g(\hat{Q}) = L_\lambda\left(\frac{P}{Q}\hat{Q}, \hat{Q}\right)$ . Note that  $Q \in \mathcal{S}$  and  $g(Q) = L_\lambda(P, Q)$ .

Consequently,  $\max_{\hat{Q} \in \mathcal{S}} g(\hat{Q}) \geq L_\lambda(P, Q)$ . Note that

$$\hat{Q} \mapsto D\left(P_{Y|X} \circ \frac{P}{Q}\hat{Q} \parallel P_{Y|X} \circ \hat{Q}\right)$$

is convex by convexity of  $(P, Q) \mapsto D(P \| Q)$ , and that

$$\hat{Q} \mapsto D\left(\frac{P}{Q}\hat{Q} \parallel \hat{Q}\right) = \sum_x \hat{Q}(x) \frac{P(x)}{Q(x)} \log \frac{P(x)}{Q(x)}$$

is linear. Thus,  $\hat{Q} \mapsto g(\hat{Q})$  is convex on  $\mathcal{S}$ . It therefore follows that  $\max_{\hat{Q} \in \mathcal{S}} g(\hat{Q})$  is obtained at an extreme point of  $\mathcal{S}$ . Since  $\mathcal{S}$  is the intersection of the simplex with a hyperplane, its extreme points are supported on at most two atoms. ■

Paired with [2, Appendix B] we get a corollary bounding  $\eta_{\text{KL}}$  in terms of the Hellinger-diameter of the channel:

$$\begin{aligned} \frac{1}{2} \text{diam}_{\text{H}^2}(P_{Y|X}) &\leq \eta_{\text{KL}} \leq g\left(\frac{1}{2} \text{diam}_{\text{H}^2}(P_{Y|X})\right) \\ &\leq \text{diam}_{\text{H}^2}(P_{Y|X}) \end{aligned} \quad (2)$$

where  $g(t) \triangleq 2t(1 - \frac{t}{2})$ ,  $\text{diam}_{\text{H}^2}(P_{Y|X}) = \sup_{x,x'} H^2(P_{Y|X=x}, P_{Y|X=x'})$  and  $H^2(P, Q) = 2 - 2 \int \sqrt{dP dQ}$ .

Note that the only property of divergence that we have used in the proof of Theorem 1 is convexity of  $(P, Q) \mapsto D(P, Q)$ . This property is shared by all  $f$ -divergences, cf. [4]. In other words we proved:

*Theorem 2:* Let  $\eta_f = \sup \frac{D_f(P_{Y|X} \circ P \| P_{Y|X} \circ Q)}{D_f(P \| Q)}$  optimized over all  $P, Q \in \mathcal{P}(\mathcal{X})$  with  $0 < D_f(P, Q) < \infty$ . Then the optimization can be restricted to pairs  $P, Q$  supported on two common points in  $\mathcal{X}$ .

This fact was conjectured in [5, Open Problem 7.4].

There are two other noteworthy results that our technique entails. First, a moment of reflection confirms that we, in fact, have shown that the upper concave envelope of the set  $\cup_{P_X, Q_X} \{(D_f(P_X \| Q_X), D_f(P_Y \| Q_Y))\}$  is unchanged if we restrict the union to pairs  $P_X, Q_X$  supported on two points.

Second, a similar argument holds for the post-SDPI coefficient of a channel [6], defined as

$$\eta_{\text{KL}}^{(p)}(P_{Y|X}) = \inf \{ \eta : I(U; X) \leq \eta I(U; Y) \quad \forall X - Y - U \}.$$

Namely, we have that  $\eta_{\text{KL}}^{(p)}$  can be computed by restricting  $X$  to take two values. Indeed, fix an arbitrary  $P_{X,Y,U}$  s.t.  $X - Y - U$ . As shown in [2, Theorem 4] one can safely assume  $U$  to be binary. Now, consider a set  $\mathcal{S}$  of all  $\hat{P}_X$  such that the joint distribution  $\hat{P}_{X,Y,U} = \hat{P}_X P_{Y|X} P_{U|Y}$  satisfies  $\hat{P}_U = P_U$ . Since  $U$  is binary,  $\mathcal{S}$  is an intersection of a hyperplane with a simplex. Now, the function  $\hat{P}_X \mapsto \hat{I}(U; X) - \lambda \hat{I}(U; Y)$  is linear in  $\hat{P}_X$  over  $\mathcal{S}$ . Consequently, the maximum (and the minimum) of this function is attained at a binary  $\hat{P}_X$ .
